Overview of the Protocol Manuscripts for the Healthy Communities Study

Russell R. Pate, PhD

Leading public health organizations, including CDC and IOM, have encouraged communities to implement programs and policies designed to increase physical activity, promote healthy eating, and reduce overweight and obesity in children.1–4 Many communities have taken on this challenge and have developed programs and policies designed to prevent or reduce obesity in young people. However, the long-term effects of these efforts remain unknown. The Healthy Communities Study (HCS) is a landmark investigation of community influences on overweight and obesity in children. It is examining the associations between characteristics of community programs and policies and obesity-related outcomes. HCS is using an innovative study design in a large-scale observational study of approximately 5000 children and their families in 130 communities across the country.

The National Heart, Lung, and Blood Institute leads the HCS, in collaboration with the Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institute of Diabetes and Digestive and Kidney Diseases, National Cancer Institute, and NIH Office of Behavioral and Social Sciences Research. Key administrative and scientific partners include Battelle Memorial Institute, University of California at Berkeley, University of South Carolina, and University of Kansas. In addition, CDC and the Robert Wood Johnson Foundation collaborated with NIH to design, develop, and implement the study.

The purpose of this series of articles is to describe the HCS study protocol. The articles by Arteaga et al.5 and John and colleagues6 provide an overview of the study and describe its rationale, organization, and implementation. The article by Sroka et al.7 describes how BMI, the primary dependent variable in the study design, was measured. The article by Fawcett and colleagues8 describes the measures and procedures used to describe community programs and policies that are aimed at obesity prevention in youth. The next two articles, by Pate et al.9 and Ritchie and colleagues,10 describe how physical activity and diet, which are key targets of community policies and programs designed to address childhood obesity, were measured. The final article, by Strauss et al.,11 describes the statistical analysis strategy and plans. The developed methods and forthcoming findings are expected to contribute to our understanding of what communities are doing to prevent child obesity and what is working. These findings are intended to enable communities across the country to effectively prioritize public health plans and activities.

Additional information on the participating organizations and a glossary of terms used in the HCS can be found at http://www.nhlbi.nih.gov/research/resources/hcs/index.shtml.

No financial disclosures were reported by the authors of this paper.
